ABSOLUTE / UPAJ

Rainfall grids, agricultural insurance and FinStac

A 10 km rainfall grid and agricultural insurance use case, with FinStac as a current public product reference.

Role: Product leadership across the Absolute portfolio | Period: October 2021–November 2024

Reported outcomes and scope

25 km → 10 km · Reported rainfall-grid resolution

27% · Reported premium reduction

The population and pricing evaluation are not included in the supplied records.

The product problem

A coarse rainfall grid can treat nearby villages as the same risk even when their conditions differ. Publicly available 25 km grids and the cost of higher-resolution data formed the starting constraint for the rainfall and insurance use case.

My role

I led product work on the rainfall capability and its insurance use case, connecting the data requirement with validation and the people using the output. The Professional Profile also describes a PMFBY crop-insurance sandbox workstream.

What I built

The approach combines satellite rainfall estimates with local weather stations, terrain and historical patterns to produce a 10 km grid. Ground-truth validation and actuarial collaboration connect the technical output with a pricing decision.

The related PMFBY sandbox is described as continuing into execution. It extends the institutional use of the rainfall capability, with the ongoing programme stage preserved separately from the earlier grid-development work.

Connecting a finer grid with a pricing task

The starting constraint was a publicly available 25 km grid and the cost of more detailed rainfall information. The project developed a 10 km by 10 km model. The Professional Profile describes satellite rainfall estimates, station observations, terrain and historical patterns as inputs, with ground-truth work across monsoon cycles.

I worked on the product use of that capability, including the actuarial collaboration that connected the grid to premium tables. A finer spatial unit was a means to give the pricing team more local information. The product case therefore joins the technical resolution requirement with a specific institutional decision rather than treating model completion as the entire delivery.

FinStac: current product reference

Upaj's FinStac page, captured in October 2026, presents personalised cover around agricultural perils and triggers. It describes crop, cattle, motor, livestock and fishery insurance, a DigiFasal DIY offering, and distribution through the app, APIs, POS agents and paravets.

The current page also describes climate resilience against heat spells, flash floods and extreme rainfall. This is a product reference for the wider agricultural-insurance setting. My historical rainfall-grid and PMFBY sandbox work is a separate contribution; the record does not establish ownership of every insurance product now listed on FinStac.

What changed

The earlier CV documents the resolution change from 25 km to 10 km and reports a 27% premium reduction for the insurance use case. The Professional Profile describes the PMFBY sandbox as continuing into execution. The percentage is a reported use-case outcome; the sandbox's ongoing stage remains distinct from completed rollout.

The lesson from this work

This case demonstrates translating data resolution into a business requirement. A more detailed grid is useful when its validation and decision use are understood, rather than treating finer resolution alone as proof of better outcomes.

Watch the current public product reference

These recordings capture Upaj's current public product information in October 2026. They provide visual context for the historical contributions described here; they do not establish ownership of every current feature.

Evidence and attribution

The premium result is source-reported; the PMFBY sandbox is described as an ongoing execution workstream.

The 27% pricing cohort, period and actuarial comparison are not attached. FinStac reference is a public-page capture dated 13 October 2026; no policy issuance or claims journey was inspected.
