CASHKARO / BANKKARO

Callable lending policy and outcome feedback

Separating policy evaluation from the chat interface, with a documented direction for cross-product reuse.

Role: Product architecture and implementation review | Period: March 2025–Present

Reported outcomes and scope

Policy separated from interface

MCP-related education-loan work is described in the supplied material.

Outcome feedback direction

Lender rejections and reviewer overrides are described as inputs to future policy work.

The product problem

A matching rule embedded in one interface is hard to reuse across products. Lender rejection reasons and reviewer overrides can also reveal gaps in the policy, but the way those signals change future decisions must remain understandable.

My role

My education-loan MCP work connects lender-rule modelling with a callable policy capability. A later working guide describes personal- and education-loan decision systems behind a shared service; this is a developing architecture account alongside the more concrete EduLoans rules portfolio.

What I built

The direction is to expose policy evaluation through MCP so a consuming product surface can call the same decision capability. The working guide describes two business-rule engines behind one MCP server, and rejection reasons and manual overrides as feedback inputs. The original technical portfolio retains deterministic matching for the first version.

Separating the policy from its interface

The working-guide architecture separates a decision capability from the interface consuming it. A chat flow, reviewer surface or another application can have a different interaction pattern while depending on a common lender-policy evaluation. The guide describes two business-rule engines behind one MCP server as the direction for that shared capability.

The initial EduLoans policy work provides the starting point: lender-specific conditions, verification before matching and a source of truth for rules. The service direction extends that work towards reuse. The lender still owns the credit decision, while the product evaluates policy and supports the application handoff.

What lender outcomes can tell the product

A rejection or underwriter override can point to a missing condition, an unsuitable route or information that was not captured early enough. The later guide describes using those outcomes to review the matching rules. Feedback is a separate part of the design from evaluating the next applicant against the current policy.

That separation matters because changing a policy affects future cases. A deterministic rule can be inspected for one applicant, while an update needs its own ownership and approval process. The workstream brings that operating question into the architecture; production use and the exact update mechanism remain at the development stage described in the source notes.

What changed

The output is a callable-policy and feedback architecture workstream alongside the working EduLoans builds. It makes the reuse and policy-change questions explicit. There is no separate measured business result for MCP reuse or feedback updates; wider marketplace conversion is covered in its own study.

The lesson from this work

This work demonstrates the distinction between an inspectable decision and a policy that can evolve. It also shows why a reusable interface needs an explicit ownership boundary between product rules, reviewer judgement and automated execution.

Visual references and walkthroughs

Documented workflow: Client requests evaluation → Callable lender-policy tool → Deterministic rule evaluation → Result returned to the interface → Reviewed outcome feedback

An authored explanation of the workflow described in this case study. This is a diagram, not a captured product screen. It includes architecture or validation directions whose production deployment is not established.

View the online case study for the full image gallery and playable videos.

Evidence and attribution

This case presents the documented architecture and direction. It does not claim automatic production retuning or full deployment across both lending products.

Two BREs and one MCP server are described in a later working guide. Exact tools, production wiring, feedback approval and live reuse remain unconfirmed; architecture direction is not a release or business-result claim.
