CREDFLOW

Pay via Credit Card for SME payments

A business-payment journey delivered alongside high-volume payment infrastructure.

Role: Senior Product Manager | Period: December 2024–March 2025

Reported outcomes and scope

□10Cr · Reported first-week transaction volume

Transaction value is distinct from revenue and reconciled settled funds.

The product problem

An SME payment feature must make the purpose of the transaction and its progress understandable while depending on reliable payment execution. A launch can bring a burst of volume, so the customer flow and the engineering capacity have to be considered together.

My role

I owned the Pay via Credit Card launch and worked with engineering on a custom payment solution suited to large-scale business transactions. The role connected the customer journey with payment-use and commercial measures.

What I built

I worked with engineering on a custom payment solution for high-volume transactions and brought the customer-facing payment flow into the wider KuberX launch. The payment delivery and the acquisition/onboarding work were connected parts of getting the app into use.

A customer flow with a money-movement dependency

The use case was an SME making business payments through a credit card. I owned the product launch and its payment journey. The engineering partnership was necessary because the flow depended on executing the transaction, not simply collecting a payment instruction on a screen.

I worked with engineering on a custom solution suited to the high-volume transactions and spike load expected at launch. Product delivery had to connect the customer action with that technical dependency. This was the payment capability brought into KuberX’s launch alongside the acquisition, analytics and onboarding work.

The payment feature inside the KuberX programme

KuberX combined payments and lending for SME users. The launch programme introduced analytics, sign-up events and onboarding changes while engineering delivered the payment capability. This connected new-user acquisition with a specific business action that users could take after joining.

The reported first-week volume gives the feature a concrete launch result. Its practical meaning is a payments measure: a payment instruction, a successful transaction and a settled business receipt are different milestones. The portfolio uses the reported transaction value as the early adoption result, with the exact state definitions retained in the source notes.

What changed

The feature reports □10 crore in transaction value during its first launch week. This captures the early scale of payment use inside the KuberX programme, separately from its acquisition-efficiency result. Transaction value describes money moving through the product, rather than the product’s fee revenue.

The lesson from this work

This case demonstrates the need to assess a payment release through both usable journeys and money movement. The launch result is meaningful when its transaction state and period remain clear.

Evidence and attribution

Payment volume is retained in the original currency and with its reported first-week period.

□10 crore is first-week transaction value, not revenue. The records do not reconcile initiated, successful and settled payments. Settlement-interface details and individual architecture authorship are incomplete.
